Bacterial Disease Mechanisms An Introduction

This introductory textbook explores bacterial disease mechanisms and bacteria-host interactions. The central premise is that bacteria have evolved by means of manipulating normal host cell functions and overcoming host defense systems to ensure their survival.

Bacteria cause disease by secreting or excreting toxins (as in botulism), by producing toxins internally, which are released when the bacteria disintegrate (as in typhoid), or by inducing sensitivity to their antigenic properties (as in tuberculosis).

This introductory cellular microbiology textbook describes how bacteria cause human diseases. It differs from other books on the subject by describing disease mechanisms in terms of the way in which bacteria subvert normal host cell functions and defence systems to ensure their own survival.

Introduction. Bacterial exotoxins are a diverse collection of proteins responsible for many of the symptoms caused by pathogens during infection. Exotoxins are actively exported by bacteria or else are released on cell lysis. Some toxins can kill cells outright by a number of different means.

Disease-causing germs can also infect you through contaminated food and water. This mechanism of transmission allows germs to be spread to many people through a single source. Escherichia coli (E. coli), for example, is a bacterium present in or on certain foods — such as undercooked hamburger or unpasteurized fruit juice.

Infectious Diseases - An Introduction

For example, bacterial pathogenesis is the mechanism by which bacteria cause infectious illness. Most diseases are caused by multiple processes. For example, certain cancers arise from dysfunction of the immune system (skin tumors and lymphoma after a renal transplant, which requires immunosuppression).
